

Suffix replacement

Task

Write a function to replace suffixes in a word, based on a mapping provided by the user. The function should be called `replace_suffix` and take two arguments:

1. a `str` containing a word form
2. a `dict` object containing a mapping from suffixes to their replacements

It should return the word with the *first* match replaced, or the word unchanged if there are no matches. See below for an example.

Note: you may assume a Python version of 3.7 or higher. This is important, since the order of elements in a `dict` object was not guaranteed to be fixed in earlier versions, and in this case the order may be important. For instance, imagine that the input `dict` object is the following:

```
{"es": "ing", "s": "ing"}
```

If you (correctly) replace the “es”, this will turn “likes” into “liking”, but if you were to replace “s” instead you would end up with “likeing”.

Put your solution in the file `morphology.py`.

Example

```
import morphology
rules = {"es": "ing", "s": "ing", "ed": "ing"}
```

```
for word in ["likes", "sings", "liked", "like", "best", "I"]:  
    print(morphology.replace_suffix(word, rules))
```

Should print the following forms: *liking, singing, liking, like, best, I*.
