

Word by word translation

Task

A (too) simple method for machine translation is to translate a text word by word. Write a function `word_by_word` that takes two arguments:

1. a `str` containing a sentence with space-separated tokens
2. a `dict` containing a lexicon, a mapping of words in the source language to words in the target languages, both represented as strings

The function should return a `str` containing the translated sentence, with space-separated tokens like the input. In case a word is not in the lexicon it should be copied unchanged to the output.

Put your code in the file `translation.py`.

Example

In [1]: `import translation`

In [2]: `translation.word_by_word( "Python is a language", {"a": "一个", "is": "是", "language": "语言"})` Out[2]: `'Python 是一个语言'`
