

Words overlap

Task

Write a function `words_overlap` which takes two arguments, both of which are strings containing comma-separated words or phrases. Return `True` if at least one of the words/phrases in the two arguments are identical.

Note that words/phrases are separated by two characters: a comma and a space. It is perfectly fine to do `somestring.split(", ")` to break such strings into lists. The most elegant way of solving this exercise includes set objects. One special case that is easy to get wrong is when both arguments are the empty string, this should count as no overlap.

Example

```
In [1]: import simple
```

```
In [3]: simple.words_overlap("one thing, two things", "one, two, three")
```

```
Out[3]: False
```

```
In [4]: simple.words_overlap("one thing, two things", "two things, monkey")
```

```
Out[4]: True
```
