

Non-mandatory exercises: A

Print

1. What will be printed in the code below?

```
print("Hello!")
```

2. In the code below, the programmer wanted the program to print the message *goodbye*.

```
print(goodbye)
```

However, running the code resulted in the error:

```
NameError: name 'goodbye' is not defined
```

Add two characters to the code to make it work as intended.

3. Is the code below correct?.

```
print('Welcome')
```

4. What happens in the code below?

```
print(2026)
```

5. Write code that uses `print()` to print your name.

Variables

6. What happens in the code below?.

```
greeting_message = "Hello!!!!"  
print(greeting_message)
```

Non-mandatory exercises: A

7. What happens in the code below?

```
current_year = 2026
print(current_year)
```

8. In the code below, the programmer has forgotten to **assign a value to the variable** `birth_year`. Therefore, the code will result in the following error:

`NameError: name 'birth_year' is not defined.`

Fix the code, so that a year is printed out.

```
birth_year                                # Code missing
print(birth_year)
```

9. Write code that assigns values to two variables. To one of variables, you are to assign the name of a person, and to the other variable you are to assign the year when this person was born. Then print the two variables.

10. What happens in the code below?

```
current_year = 2026
year_to_print = current_year + 1
print(year_to_print)
```

11. What happens in the code below?

```
current_year = 2026
year_to_print = current_year + 1
print(current_year)
```

Non-mandatory exercises: A

12. What happens in the code below?

```
current_year = 2026
year_to_print = current_year + 1
print("current_year")
```

13. What happens in the code below?

```
current_year = 2026
last_year = current_year - 1
print(last_year)
```

14. What happens in the code below?

```
current_year = 2026
print(current_year - 1)
```

15. Write a new version of the code below, so that it instead assigns the result of `current_year + 10` to a variable, and prints out that variable.

```
current_year = 2026
print(current_year + 10)
```

16. What happens in the code below?

```
year = 2026
year = year + 1
print(year)
```

Non-mandatory exercises: A

17. The code below prints 2026 twice. Add one line of code so that it instead prints 2026 the first time and 3026 the next time.

```
year = 2026
print(year)
```

```
print(year)
```

18. The code below will result in an error. Why? Fix it so it prints *2025*.

```
current_year = 2026
last-year = current_year - 1 # incorrect code line
print(last-year) # incorrect code line
```

19. The code below does not work. Why?.

```
1st_year = 2026 # incorrect code line
2nd_year = 2027 # incorrect code line
print(1st_year) # incorrect code line
print(2nd_year) # incorrect code line
```

20. What happens in the code below?

```
#print("Hello!")
```

21. What is printed below?

```
year = 2026
greeting = "Hello!!!"
print(type(year))
print(type(greeting))
```

Non-mandatory exercises: A

Importing a file in the Python prompt

22. Let's say that you have created a file called `greeting.py`, with the following content:

```
welcome_greeting = "Welcome"  
print("Hi")  
print("Goodbye")  
print(welcome_greeting)
```

and then write:

```
import greeting
```

in the Python prompt?

What happens if you write:

```
import greeting
```

again?

What happens if you exit the Python prompt and do the same import again?

(You exit the Python prompt by typing `exit()`)

23. Let's say that you have created a file called `greeting_variables.py`, with the following content:

```
morning_greeting_informal = "Morning"  
goodbye_informal = "Bye"  
hello_informal = "Hi"  
  
if __name__ == "__main__":  
    print(morning_greeting_informal)  
    print(goodbye_informal)  
    print(hello_informal)
```

and then write:

```
import greeting_variables
```

in the Python prompt?

What happens then?

Non-mandatory exercises: A

Running python code from the Unix prompt

24. Assuming the same content in `greeting_variables.py` as in the previous question: What happens if you write the following in the **Unix prompt**:

```
python3 greeting_variables.py
```
