

Finding words of a given part of speech

Task

Write a function `find_pos` which takes two arguments:

1. a list of tuples, where each tuple consists of a `str` representing a word and another `str` representing its part of speech (VERB, ADV, PRON, CCONJ, PROPN, etc.).
2. a `str` representing the part of speech we want to find.

The function should return a list of strings containing all words in the input belonging to the specified part of speech. If a word occurs more than once, it should occur as many times in the return value as in the input.

Put your code in the file `syntax.py`.

Example

The following code should print the two verbs in the text: `['love', 'use']`

```
import syntax

text = [('I', 'PRON'), ('love', 'VERB'), ('Python', 'PROPN'),
        ('and', 'CCONJ'), ('use', 'VERB'), ('it', 'PRON'),
        ('constantly', 'ADV')]
print(syntax.find_pos(text, "VERB"))
```
